## DATA COLLECTION DESCRIPTION

The Survey of Inmates of Local Jails, 1983: [United States] (SILJ), is one of a series of data collection efforts begun in the early 1970's to assist policy makers and planners to ascertain the characteristics of the inmate population, and to assess and overcome the deficiencies in the nation's jails. The first Jail Inmate Survey was conducted in 1972 (archived under ICPSR 7668), and the second, in 1978 (archived under ICPSR 7751).

Jail is often the first place of confinement for persons who enter the criminal justice system. Thus, unlike prisons, jails house both convicted (such as persons sentenced and awaiting sentence) and unconvicted persons (such as persons in the process of and awaiting trial and persons who have not yet been formally arraigned). Given the nature of the jail population, the Bureau of Justice Statistics collected this information to provide an accurate description of the population confined in the nation's jails.

Designed to complement the Census of Inmates of Local Jails, 1983 undertaken simultaneously, the Survey of Inmates of Local Jails, 1983 gathered extensive information on current offenses, prior criminal record, detention status, drug and alcohol use, demographic and socioeconomic characteristics, military service, jail activities, and health care provided by the jails.

For the 1983 jail survey a sample of 5,785 respondents was selected from a population of roughly 223,600 male and female inmates. Of that 223,600, approximately 207,800 inmates were male and 15,800 were female. The sample included 407 institutions throughout the United States and 3,992 male and 1,793 female respondents. Individual interviews were conducted in local jails by trained U.S. Bureau of the Census interviewers.

In all, data were collected on 1,036 variables (ICPSR study consists of 1,040 variables which include 4 ICPSR identification variables). A copy of the actual questionnaire used to collect information may be found on page 589 of the codebook.

## SAMPLE DESIGN, ESTIMATION PROCEDURE, AND RELIABILITY OF THE ESTIMATES

### Sample Design

The sample of inmates for the Survey of Inmates of Local Jails, 1983: [United States] was selected from a universe of approximately 3600 institutions containing roughly 207,800 males and 15,800 females. The universe of institutions was constructed and is maintained by the Bureau of the Census. Approximately 4300 males and 1800 females were to be designated for interview from a sample of roughly 400 institutions.

As a first step, all institutions were sorted by the size of their male population. Institutions containing females only were placed at the end of this list. The 181 institutions of male population size 225 or greater were designated to be in the sample with certainty. These institutions comprised stratum 1 for both the male and female samples and contained slightly more than half the total inmate population. In each of the institutions in this stratum, males were sampled at 1 in 44 and females were sampled at 1 in 6.

Strata 2 and 3 were designed to sample females only. Stratum 2 consisted of all institutions that only housed females. There were 16 such institutions and all were included in the sample with certainty. The female inmates in these institutions were sampled at 1 in 6. Stratum 3 was comprised of institutions which contained both males and females and which had at least 15 females. These institutions numbering 63, were also included with certainty, and the females were sampled at 1 in 6. Males were not eligible for sample selection in this stratum.

Stratum 4 was defined for both the male and female sample. It contained institutions housing both males and females, with male populations that were greater than 20 but less than 225, and with female populations that were less than 15. This stratum also consisted of the 63 institutions that were in stratum 3, but only the male population was eligible for sample selection in this stratum. Institutions were selected at 1 in 11, and the male inmates within selected institutions were sampled at 1 in 4. Eligible females, those numbering less than 15 in selected institutions, were sampled at 1 in 1. Females in institutions in stratum 3, were not eligible for selection in this stratum.

Stratum 5 was also defined for both the male and female samples. It contained institutions which housed males and females, with male populations totaling less than 21 and female populations totaling less than 15. These institutions were sampled at 1 in 44. Inmates were sampled from selected institutions at 1 in 1.

The sampling procedures described above generated 407 unique sample institutions and a designated sample size of roughly 6400 inmates. (Actually, 411 sample institution identification numbers were generated because 4 institutions in stratum 3 were also in stratum 4.).

The sample was self-weighting for males, such that each male inmate record received a basic weight of 44.0000. A self-weighting sample for females was impossible because of the over-all sample limitations, therefore, weights of 6.0000, 11.0000 and 44.0000 were applied to selected female records.

Approximately 6430 inmates were selected for interview. Of these, roughly 140 were ineligible because they had been released prior to the day of sample selection. Of the remaining 6290 inmates, interviews were not obtained from approximately 500 because the inmates had been released after sampling day (160), had refused to participate in the interview (170), or for other assorted reasons (170). The noninterview rate for this survey was roughly 8 percent.

- 1/ All institutions with male population 225 or greater.
- 2/ All Female-only Institutions.
- 3/ All Male/Female Institutions with 15 or more females.
- 4/ All Male/Female Institutions with male population less than 225 and greater than 20. This Stratum also included the 63 institutions in Stratum 3. Females in these institutions were not eligible for sample selection in this stratum.
- 5/ All Male/Female Institutions with less than 21 males.
- 6/ These numbers reflect the known universe at the time the sample was selected. Because of growth in the population, at the time the study was actually done, the universe included more male and female inmates.
- 7/ The actual number of institutions was 407. Four institutions in Stratum 3 were also hit in Stratum 4.

### Estimation Procedure

The estimation procedure for the 1983 SILJ consisted of: a basic weight, an institution noninterview adjustment, an inmate noninterview adjustment, and ratio adjustment to the count of inmates obtained from the 1983 Census of Local Jails.

- A. **BASIC WEIGHT.** Each inmate data record was weighted by the reciprocal of the inmate's probability of selection. For males, the basic weight was 44.0000. For females, the basic weights were 6.0000, 11.0000 and 44.0000.
- B. **INSTITUTION NONINTERVIEW ADJUSTMENT.** This factor was applied to inmate data record to account for the inmate population in institutions for which we were unable to obtain any interviews or demographic information.
- C. **INMATE NONINTERVIEW ADJUSTMENT.** This factor was applied to adjust the weights of all interviewed inmate data records to account for the noninterviewed inmates for which we were only able to obtain some basic demographic data from the inmate records. The adjustment was made within 36 different classes and was done separately for men and women. The classes (noninterview cells) were defined by race (Black, non-Black), age (less than 20, 20-24, 25+), size of facility, and detention status (convicted, unconvicted). The three size-of-facility categories for males were: male/female facilities with less than 21 males, male/female facilities with at least 21 males but less than 225 males, and male/female facilities with 225 males or greater. For females, the categories were: male/female facilities containing less than 225 males, female-only facilities, and male/female facilities with more than 225 males. The noninterview adjustment for any cell was defined as the ratio of the weighted number of interviewed plus noninterviewed inmates in a cell to the weighted number of interviewed inmates in the cell.
- D. **RATIO ADJUSTMENT.** The final step in the weighting procedure was a single cell ratio adjustment to the count of inmates by sex, obtained from the 1983 Census of Local Jails. The adjustment is defined as the ratio of the total number of inmates from the census, male or female, to the weighted estimate of inmates, male or female, from the survey.

### Reliability of the Estimates

Since the SILJ estimates are based on a sample, they may differ somewhat from the figures that would have been obtained if a complete census had been taken using the same questionnaire, instructions, and enumerators. There are two types of errors possible in an estimate based on a sample survey--sampling and nonsampling. The standard errors provided for this report primarily indicated the magnitude of the sampling errors. They also partially measure the effect of some nonsampling errors in response and enumeration, but do not measure any systematic biases in the data. The full extent of nonsampling error is unknown. Consequently, particular care should be exercised in the interpretation of figures based on a relatively small number of cases or on small differences between estimates.

**NONSAMPLING VARIABILITY.** As in any survey work, the results are subject to errors of response and nonreporting, in addition to sampling variability. Nonsampling errors can be attributed to many sources, such as inability to obtain information about all cases in the sample, definitional difficulties, differences in the interpretation of questions, inability or unwillingness to provide correct information on the part of respondents, inability to recall information, errors made in collection such as in recording or coding the data, errors made in processing the data, errors made in estimating values for missing data, and failure to represent all jails with the sample (undercoverage). Undercoverage in the SILJ results from missed institutions and missed inmates within sample institutions. Overall undercoverage for males and females, as compared to the level of the 1983 Census of Inmates of Local Jails, was roughly 6 percent and 7 percent, respectively.

**SAMPLING VARIABILITY.** The standard errors given in the following tables are primarily measures of sampling variability, that is, of the variations that occurred by chance because a sample rather than the entire inmate population was surveyed. The sample estimate and its estimated standard error enable one to construct confidence intervals, ranges that would include the average results of all possible samples with a known probability. For example, if all possible samples are selected and each of these samples surveyed under essentially the same general conditions using the same sample design, and an estimate and its estimated standard error were calculated from each sample, then:

1. Approximately 68 percent of the intervals from one standard error below the estimate to one standard error above the estimate would include the average result of all possible samples.
2. Approximately 90 percent of the intervals from 1.6 standard errors below the estimate to 1.6 standard errors above the estimate would include the average result of all possible samples.
3. Approximately 95 percent of the intervals from two standard errors below the estimate to two standard errors above the estimate would include the average result of all possible samples.

The average estimate derived from all possible samples is or is not contained in any particular computed interval. However, for a particular sample, one can say with a specified confidence that the average estimate derived from all possible samples is included in the confidence interval.

Standard errors may also be used to perform hypothesis testing, a procedure for distinguishing between population parameters using sample estimates. The common type of hypothesis appearing that may be listed is: 1) the population parameters are identical versus, 2) they are different. An example of this type of test would be comparing the proportion of unconvicted males versus the proportion of unconvicted females. Tests may be performed at various levels of significance, where a level of significance is the probability of concluding that the parameters are different when, in fact, they are identical. Statements of comparison should generally pass a hypothesis test at the 0.10 level of significance or better, and at the 0.05 level of significance or better. is preferred. This means that, for most differences, the estimated difference between parameters is greater than twice the standard error of the difference. For other differences, the estimated difference between parameters may be between 1.6 and 2.0 times the standard error of the difference. When this is the case, the statement of comparison should be qualified in some way; such as, by the use of the phrase "some evidence."

**NOTE WHEN USING SMALL ESTIMATES.** Estimates and summary measures such as medians, rates and percent distributions should be used only when the base is 300 or better for males and total persons and 100 females. Because of the large standard errors involved, there is little chance that estimates and summary measures would reveal useful information when computed on a smaller base. Estimated numbers smaller than 300 for males or total persons and 100 for females may be shown in the data tables to permit such combinations of the categories to serve each data users' needs.

**STANDARD ERROR TABLES AND THEIR USE.** In order to derive standard errors that would be applicable to a large number of estimates and could be prepared at a moderate cost, a number of approximations were required. Therefore, instead of providing an individual standard error for each estimate, generalized sets of standard errors are provided for various types of characteristics. As a result, the sets of standard errors provided give an indication of the order of magnitude of the standard error of an estimate rather than the precise standard error.

The figures presented in Tables 1 through 4 are approximations to standard errors of various estimates. Standard errors for intermediate values not shown in the generalized tables of standard errors may be approximated by interpolation.

Two parameters were used (denoted "a" and "b") to calculate standard errors for all characteristics for males, females, and total persons; they are presented in Table 5. These parameters were used to calculate the standard errors in Tables 1 through 4. They also may be used to directly calculate the standard errors for estimated numbers and percentages. Direct computation of the standard errors will give more accurate results than the use of interpolation in the standard error tables. Methods for direct computation are given in the following paragraphs.

**STANDARD ERRORS OF ESTIMATED NUMBERS.** The approximate standard error,  $\sigma(x)$ , of an estimated number shown in this report can be obtained by use of formula (1).

$$\text{Sigma} = \sqrt{\frac{x^2}{ax + bx}} \quad (1)$$

Here  $x$  is the size of the estimate and  $a$  and  $b$  are the parameters from Table 5 associated with the particular estimate.

ILLUSTRATION OF THE COMPUTATION OF THE STANDARD ERROR OF AN ESTIMATED NUMBER. Assume that a data table shows that 18,716 male inmates had burglary as their current offense. Through linear interpolation, Table 1 shows the standard error sigma( $x$ ) on an estimate of this size to be approximately 940.

The 68 percent confidence interval as shown by the data is from 17,776 to 19,656. Therefore, a conclusion that the average estimate derived from all possible samples lies within a range computed in this way would be correct for roughly 68 percent of all possible samples. Similarly, we could conclude with 95 percent confidence that the average estimate derived from all possible samples lies within the interval from 16,836 to 20,596, such as  $18,716 + (2 \times 940)$  or  $18,716 - (2 \times 940)$ . As an alternative, using formula (1) and the parameters  $a = -.000251$  and  $b = 52.24$  from Table 5 gives an estimate of the standard error to be 943.

STANDARD ERRORS OF ESTIMATED PERCENTAGES. The reliability of an estimated percentage, computed using sample data for both numerator and denominator, depends on both the size of the percentage and the size of the total upon which this percentage is based. Estimated percentages are relatively more reliable than the corresponding estimates of the numerators of the percentages, particularly if the percentages are 50 percent or more. The approximate standard error, sigma( $x,p$ ), of an estimated percentage can be obtained by use of formula (2), from which the standard errors in Tables 2,3, and 4 were obtained.

$$\text{Sigma}_{(x,p)} = \sqrt{\frac{b(p)(100-p)}{x}} \quad (2)$$

Here  $x$  is the size of the subclass of the characteristic which is the base of the percentage,  $p$  is the percentage ( $0 < p < 100$ ), and  $b$  is the parameter in Table 5 associated with the particular type of characteristic in the numerator of the percentage.

x

ILLUSTRATION OF THE COMPUTATION OF THE STANDARD ERROR OF A PERCENTAGE. Assume further, that of these 18,716 male inmates, 36.9 percent had less than an eighth-grade education. Through linear interpolation, Table 2 shows the standard error sigma (x) of 36.9 percent on a base of 18,716 to be approximately 2.5 percent. Consequently, the 68 percent confidence interval is from 34.4 to 39.4 percent. Therefore, a conclusion that the average estimate derived from all possible samples lies within a range computed in this way would be correct for roughly 68 percent of all possible samples. Similarly, we could conclude with 95 percent confidence that the average estimate derived from all possible samples lies within the interval from 31.9 to 41.9 percent, i.e.,  $36.9 + (2 \times 2.5)$  and  $36.9 - (2 \times 2.5)$  percent. As an alternative, using formula (2), and the parameter b = 52.24 from Table 5, the standard error of an estimate of 36.9 percent is

$$\sqrt{\frac{52.24 (36.9 \times 63.1)}{18,716}} = 2.5 \text{ percent}$$

STANDARD ERROR OF A DIFFERENCE. For a difference between two sample estimates, the standard error is approximately equal to

$$\sigma_{(x-y)} = \sqrt{\frac{\sigma_x^2 + \sigma_y^2}{2}} \quad (3)$$

where  $\sigma_x$  and  $\sigma_y$  are the standard errors of the estimates x and y; the estimates can be of numbers, percents, ratios, and the like. This will represent the actual standard error quite accurately for the difference between two estimates of the same characteristic in two different areas, or for the difference between separate and uncorrelated characteristics in the same area. If, however, there is a high positive (negative) correlation between two characteristics, the formula will overestimate (underestimate) the true standard error.

ILLUSTRATION OF THE COMPUTATION OF THE STANDARD ERROR OF A DIFFERENCE BETWEEN ESTIMATED PERCENTAGES. Assume that a data table shows that 31.1 percent of all female inmates (15,770) had 12+ years of education, and the corresponding percentage for male inmates (207,780) was 23.7 percent. Thus, the apparent difference in percents of inmates with 12+ years of education between males and females is 7.4 percent. Using formula (3), the standard error of the estimated difference of 7.4 percent is about

$$\sqrt{(.9)^2 + (.7)^2} = 1.1 \text{ percent}$$

(The standard errors, .9 and .7, were obtained by use of formula (2). ) This means the 68-percent confidence interval around the difference is from 6.3 to 8.5 percent. Therefore, a conclusion that the average difference derived from all possible samples lies within a range computed in this way would be correct for roughly 68 percent of all possible samples. Similarly, we could conclude with 95-percent confidence that the average difference derived from all possible samples lies within the interval from 5.2 to 9.6 percent, or,  $7.4 \pm (2 \times 1.1)$  percent. Since this interval does not include zero, we can conclude with 95-percent confidence that the percentage of female inmates with 12+ years of education is greater than the percentage of male inmates with 12+ years of education.

## FILE STRUCTURE

The Survey of Inmates of Local Jails, 1983: [United States] is available from the ICPSR in two formats: card image and OSIRIS. The card image file contains several decks per case in a format based on 80 column punched cards. The data are sorted by case with all decks for a case together in ascending order.

The OSIRIS dictionary gives the format and other information for each variable in the OSIRIS data file. The dictionary or dictionary-codebook file is used in conjunction with the OSIRIS software package. The OSIRIS data file is constructed with a single logical record for each case. There are 1040 variables on 5785 cases.

## CODEBOOK INFORMATION

The example below is a reproduction of information appearing in the machine-readable codebook for a typical variable. The numbers in brackets do not appear but are references to the descriptions which follow this example.

[1] VAR 0409 [2] Q.30H 2ND SNT MAX: YRS [3] MD=99 OR GE 98  
REF 0409 [4] LOC 863 WIDTH 2 [5] DK 12 COL 33  
[6] IMP DEC=d

[7] Q.30h (2a) What was the maximum sentence length  
of your sentence: [years]? [Second time served]

[8] SEE NOTE(S) X

[9] Actual number is coded.

[10] [11]

00. Less than one year

98. Not Reported

99. Out of Universe

- [1] Indicates the variable and reference numbers. A variable number and a reference number are assigned to each variable in the data collection. In the present codebook which documents the archived data collection these numbers are identical. Should the data be subsetted or rearranged by an OSIRIS program (e.g., MMP to intersperse data from another source, or TCOT to produce an analysis deck), the variable numbers would change to reflect the order of the new data collection, while the reference number would remain unchanged to reflect the variable number in the codebook describing the archived data collection.
- [2] Indicates the abbreviated variable name (maximum of 24 characters) used in the OSIRIS system to identify the variable for the user. An expanded version of the variable name can be found in the variable description list.
- [3] Indicates the code values of missing data. In this example, code values equal to 99 or greater than or equal to 98 are missing data (MD=99 OR GE 98). Alternative statements for other variables are "MD=0," "MD GE 9," or "NO MISSING DATA CODES." Some analysis software packages (including the OSIRIS software package) require that certain types of data which the user desires to be excluded from analysis be designated as "MISSING DATA," e.g., inappropriate, unascertained, unascertainable, or ambiguous data categories. Although these codes are defined as missing data categories, this does not mean that the user should not or cannot use them in a substantive role if so desired.
- [4] Indicates the starting location and width of this variable when the data are stored on a magnetic tape in the OSIRIS format. If the variable is of a multiple-response type, the width referenced is that of a single response. In this example the variable named "Q.3OH 2ND SNT MAX: YRS" is 2 columns wide and is located in the 863rd column within the record.
- [5] Indicates the location by deck and column(s) of this variable when the data are stored on cards or in card-image format (80-column format)
- [6] A variable containing data with implied decimals is denoted by the message "IMP DEC=d," where d is the number of decimal places implied in the variable.

- [7] This is basically the full question text supplied by the investigator. The portion of the question number that is enclosed in parentheses, "(" and ")", have been added by ICPSR processors to make the question number unique. Similarly, text enclosed in brackets, "[" and "]", have been added by ICPSR processors to make the question clear when it is separated from other questions or make it unique. The actual question text can be found in the questionnaire which is at the end of the codebook.
- [8] A variable which has a footnote associated with it is denoted by the message, "SEE NOTE(S) X" where X is the number of the footnote referenced.
- [9] "Actual number is coded" appears in the codebook to indicate that the variable has been declared continuous.
- [10] Indicates the code values occurring in the data for this variable.
- [11] Indicates the textual definitions of the codes. Abbreviations commonly used in the code definitions are "DK" (Do Not Know), "NA" (Not Ascertained), and "INAP" (Inappropriate).

#### ICPSR PROCESSING INFORMATION

The data collection was processed according to the standard ICPSR processing procedures. The data were checked for illegal or inconsistent code values which, when found, were recoded to OSIRIS missing data values. No consistency checks were performed. Statements bracketed in "<" and ">" signs in the body of the codebook were added by the processors for explanatory purposes.

## APPENDIX

## \*\*\* NOTE 1 \*\*\*

The following table consists of a column of new codes a column of old codes and a listing of the offenses that these numbers represent. While the old codes are two columns long, the new codes are three columns long. The reason for this difference is that the third column of the new offense codes defines the degree of completion of the offense. A zero (0) in the third column means the crime was completed. A one (1) means it was attempted. A two (2) means the offense was a conspiracy.

In addition to the crime codes, two non-response codes are included in the table below. The first, code 008 means respondent did not give answers for Q.7a-e, Q.8a-h, Q.9a-m. The other non-response code, 009, means the respondent did not remember past offenses.

Equivalent alphabetic codes follow this numeric listing.  
Either code may be used.

New code	Old code	Description

## \*\*\* NOTE 3 \*\*\*

**Most Serious Offense**

The variable Most Serious Offense (MSO) was derived in the following way. Each record was first screened on SC 0004, Detention Status to determine the offender's conviction status. For offender's who had no offenses or for whom detention status was unable to be determined, no MSO was recorded. For offenders who were either convicted or unconvicted, the next step was to determine how many offenses were listed in SC 1034; SC 1036; SC 1038; SC 1040; SC 1042.

If only one offense was listed, the most serious offense for which the offender was convicted was used as the (MSO). If the offender was unconvicted for all offenses, the most serious of the offenses listed was used. The MSO was determined by reference to the ranking system that follows. The lower the rank, the more serious the offense.

This ranking system was first developed for use in the 1979 Survey of Inmates of Adult State Correctional Facilities. It was developed based on the criminal codes and maximum range of sentences that could be imposed for each offense in six states: Georgia, Illinois, Mississippi, New York, Pennsylvania and the Bureau of Prisons. Offenses in each state were rank ordered on the maximum range of sentences that could be imposed. In those instances where the same range was attached to more than one offense, offenses with any violence were ranked as more serious.

Based on the data from all six jurisdictions a median sentence length for each offense was determined. These calculated values were then compared to the actual median sentence lengths received in the 1978 Survey of Inmates of Local Jails (SILJ). Additionally, the median amount of bail set for specific offenses in the 1978 SILJ which was thought to be related to the severity of the crime was also examined. The result form these efforts was the ranking system used in the 1979 Survey.

In April 1984, the above procedure using four States - Georgia, Illinois, Mississippi, and New York - was replicated to determine if the established rankings for the 1979 Survey still applied. The procedure outlined above was used to determine the median sentence length for each offense. In general, the rankings from this update did not deviate markedly from the 1978 results. As such, the 1979 ranking scale was adapted for use in the 1983 SILJ with minor modifications.
